Q Learning is a value-based RL algorithm

$$Q^{\pi}(s_t, a_t) = \underline{E}[R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots | s_t, a_t]$$

Q-Values for the state
given a particular state

Expected discounted
cumulative reward

Given the state and action

Discussion

Deep Q Learning

Deep Q Learning

- ▶ How can we use the basics of Q Learning without having to store a q-table?
 - universal approximation theorem
 - use neural network as approximation to q function

Implementation of a Deep Q Learning Agent

Reinforcement
Learning for
playing
Connect Four

Simon Hölck,
Florian Cimander,
Tim Löhner

1. Neural Network

- ▶ used eight fully connected layers to have enough depth for good approximation
- ▶ added three dropout layers to prevent overfitting
- ▶ used relu as activation function in forward pass

2. Exploration vs. Exploitation

- ▶ Exploration: Agent makes out of character decisions that are not given by the network (random)
 - ▶ Exploitation: Agent takes actions given by the network
- We use *epsilon decay* to find the right balance between the two

3. Learning Process

- ▶ Two problems
 - a) correlated inputs/outputs
 - b) non-stationarity

Implementation of a Deep Q Learning Agent

Discussion

3. Learning Process

- ▶ for every action during a game the following quintuple is stored to the agents *experience replay memory*
(state, action, reward, new state, done)
- ▶ rewards are determined when game is finished
- ▶ the agent learns the saved transitions in batches that are chosen randomly from its memory

→ solves the problem of correlated inputs/outputs

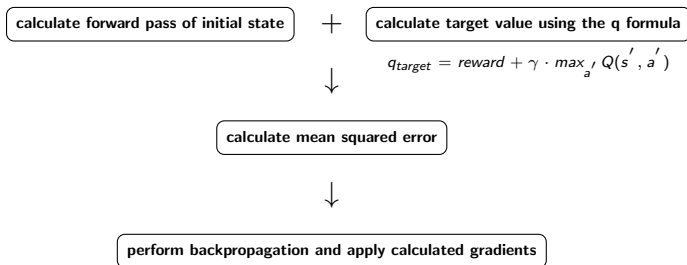

Implementation of a Deep Q Learning Agent

Reinforcement
Learning for
playing
Connect Four

Simon Hölck,
Florian Cimander,
Tim Löh

3. Learning Process

- ▶ for each transition in the batch we perform the following steps

Reinforcement
Learning

Q Learning

Deep Q Learning

Training

Discussion

3. Learning Process

- ▶ we deal with this problem by using a *target network*
- ▶ the target network is an old version of the underlying DQN network
- ▶ it gets updated very infrequently

→ targets stay constant and problem becomes more stationary

Discussion

Opponent: Minimax

Self-play RL like Alpha Zero is too time consuming.
Solution: Let the Neural Network practice against Minimax

Learning over time

Reinforcement
Learning for
playing
Connect Four

Simon Hölck,
Florian Cimander,
Tim Löhrl

We started by letting the Neural Network train **50000**
Episodes against Minimax with depth = 1

Reinforcement
Learning

Q Learning

Deep Q Learning

Training

Best Practices

Demo

Discussion

Save the trained model and start all-over again

Now this 99% ratio Neural Network plays and practices against the Minimax with depth = 2

Best Practices

Trial and Error, Error ... and more Errors

Best set of Hyperparameters so far:

- ▶ Randomness 100% with exponential fall down to fixed 1%
- ▶ Batch Size = 128
- ▶ Memory size = 50000
- ▶ Learning Rate for the Neural Network = 0.01
- ▶ Episodes 50000 on depth = 1: *15 hours*
- ▶ Episodes 10000 on depth = 2: *10 hours*

Demo

It is time to show a Demo in the GUI

Discussion

Discussion

playing
Connect Four

Simon Hölck,
Florian Cimander,
Tim Löhrl

- ▶ Does a 100% win ratio against Minimax of depth 5 or 6 plays good against human opponents?
- ▶ Can the Neural Network generalize better if we would have used the Monte Carlo Tree Search (MCTS) as opponent instead of the Minimax?
- ▶ Could a ResNet train a better AI against human players with everything else kept the same than our very basic Neural Network architecture?
